

CS/SE 3340 Computer Architecture

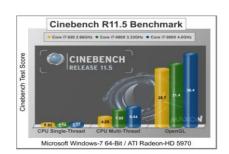

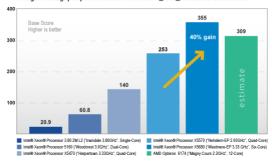

Introduction to Computer Performance

Adapted from "Computer Organization and Design, 4th Ed." by D. Patterson and J. Hennessy

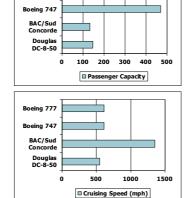

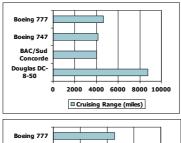

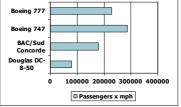

Intel* Xeon* Processor 5600 series-based Server platforms
Integer throughput performance on SPECint*_rate_base2006 benchmark

• Which airplane has the best performance?

3

Response Time and Throughput

- Response time
 - How long it takes to do a task
- Throughput
 - Total work done per unit time
 - e.g., tasks/transactions/... per hour
- How are response time and throughput affected by
 - Replacing the processor with a faster version?
 - Adding more processors?
- We'll focus on response time for now...

Relative Performance

- Define Performance = 1/Execution Time
- "X is n time faster than Y"

Performanc e_x /Performanc e_y = Execution time_y/Execution time_x = n

- Example: time taken to run a program
 - 10s on A, 15s on B
 - Execution Time_B / Execution Time_A= 15s / 10s = 1.5
 - So A is 1.5 times faster than B

How to measure 'Execution Time'?

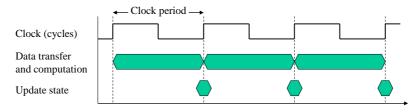

5

Measuring Execution Time

- Elapsed time
 - Total response time, including all aspects
 - Processing, I/O, OS overhead, idle time
 - Determines system performance
- <u>CPU time</u>
 - Time spent processing a given job by the CPU
 - Discounts I/O time, other jobs' shares
 - Comprises user CPU time and system CPU time
 - Different programs are affected differently by CPU and system performance

CPU Clocking

Operation of digital hardware governed by a constant-rate clock

- Clock period: duration of a clock cycle
 - e.g., $250ps = 0.25ns = 250 \times 10^{-12} sec$
- Clock frequency (rate): cycles per second
 - e.g., 4.0GHz = 4000MHz = 4.0×10^9 Hz

7

CPU Time

CPUTime = CPUClock Cycles × Clock Cycle Time $= \frac{\text{CPUClock Cycles}}{\text{Clock Rate}}$

- CPU performance improved by
 - Reducing number of clock cycles
 - Increasing clock rate
 - Hardware designer must often trade off clock rate against cycle count

CPU Time Example

- Computer A: 2GHz clock, 10s CPU time
- Designing Computer B
 - Aim for 6s CPU time
 - Can do faster clock, but causes 1.2 × clock cycles
- How fast must Computer B clock be?

$$\begin{aligned} \text{Clock Rate}_{\text{B}} &= \frac{\text{Clock Cycles}_{\text{B}}}{\text{CPUTime}_{\text{B}}} = \frac{1.2 \times \text{Clock Cycles}_{\text{A}}}{6\text{s}} \\ \text{Clock Cycles}_{\text{A}} &= \text{CPUTime}_{\text{A}} \times \text{Clock Rate}_{\text{A}} \\ &= 10\text{s} \times 2\text{GHz} = 20 \times 10^9 \\ \text{Clock Rate}_{\text{B}} &= \frac{1.2 \times 20 \times 10^9}{6\text{s}} = \frac{24 \times 10^9}{6\text{s}} = 4\text{GHz} \end{aligned}$$

9

Instruction Count and CPI

Clock Cycles = Instructio n Count \times Cycles per Instructio n

CPU Time = Instructio n Count \times CPI \times Clock Cycle Time $= \frac{\text{Instructio n Count} \times \text{CPI}}{\text{Clock Rate}}$

- Instruction Count for a program
 - Determined by program, ISA and compiler
- Average cycles per instruction
 - Determined by CPU hardware
 - If different instructions have different CPI
 - Average CPI affected by instruction mix

CPI Example

- Computer A: Cycle Time = 250ps, CPI = 2.0
- Computer B: Cycle Time = 500ps, CPI = 1.2
- Same ISA
- Which is faster, and by how much?

11

CPI in More Detail

 If different instruction classes take different numbers of cycles

$$Clock\ Cycles = \sum_{i=1}^{n} (CPI_{i} \times Instructio\ n\ Count_{i})$$

Weighted average CPI

$$CPI = \frac{Clock \ Cycles}{Instructio \ n \ Count} = \sum_{i=1}^{n} \left(CPI_{i} \times \frac{Instructio \ n \ Count}{Instructio \ n \ Count} \right)$$

$$\frac{Relative}{frequency}$$
12

CPI Example

 Alternative compiled code sequences using instructions in classes A, B, C

Class	А	В	С
CPI for class	1	2	3
IC in sequence 1	2	1	2
IC in sequence 2	4	1	1

- Sequence 1: IC = 5
 - Clock Cycles= 2×1 + 1×2 + 2×3

= 10

• Avg. CPI = 10/5 = 2.0

- Sequence 2: IC = 6
 - Clock Cycles= 4×1 + 1×2 + 1×3

= 9

• Avg. CPI = 9/6 = 1.5

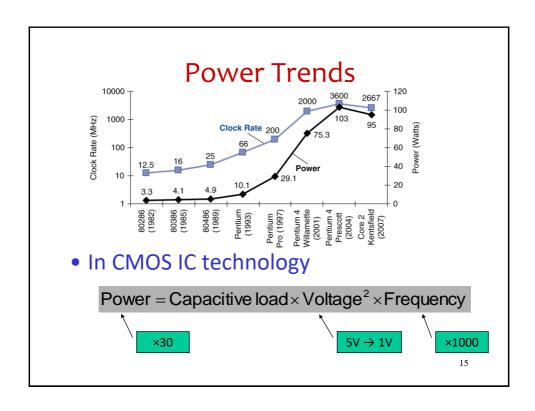

13

Performance Summary

The BIG Picture

 $CPUTime = \frac{Instructio \ ns}{Program} \times \frac{Clock \ cycles}{Instructio \ n} \times \frac{Seconds}{Clock \ cycle}$

- Performance depends on
 - Algorithm: affects IC, possibly average CPI
 - Programming language: affects IC, average CPI
 - Compiler: affects IC, average CPI
 - Instruction set architecture: affects IC, average CPI, T_c

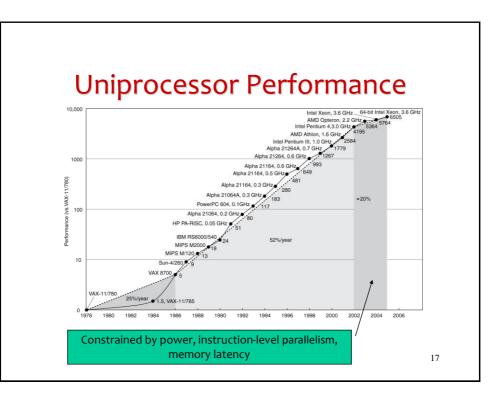

Reducing Power

- Suppose a new CPU has
 - 85% of capacitive load of old CPU
 - 15% voltage and 15% frequency reduction

$$\frac{P_{\text{new}}}{P_{\text{old}}} = \frac{C_{\text{old}} \times 0.85 \times (V_{\text{old}} \times 0.85)^2 \times F_{\text{old}} \times 0.85}{C_{\text{old}} \times V_{\text{old}}^{\ 2} \times F_{\text{old}}} = 0.85^4 = 0.52$$

- The power wall
 - We can't reduce voltage further
 - We can't remove more heat
- How else can we improve performance?

Multiprocessors

- Multicore microprocessors
 - More than one processor per chip
- Requires explicitly parallel programming
 - Compare with instruction level parallelism
 - Hardware executes multiple instructions at once
 - Hidden from the programmer
 - Hard to do
 - Programming for performance
 - Load balancing
 - Optimizing communication and synchronization

Pitfall: MIPS as a Performance Metric

- MIPS: Millions of Instructions Per Second
 - Doesn't account for
 - Differences in ISAs between computers
 - Differences in complexity between instructions

$$\begin{split} \text{MIPS} = & \frac{\text{Instructio n count}}{\text{Execution time} \times 10^6} \\ = & \frac{\text{Instructio n count}}{\frac{\text{Instructio n count} \times \text{CPI}}{\text{Clock rate}}} \times 10^6} = \frac{\text{Clock rate}}{\text{CPI} \times 10^6} \end{split}$$

CPI varies between programs on a given CPU

19

Pitfall: Amdahl's Law

• Improving an aspect of a computer and expecting a proportional improvement in overall performance

$$T_{improved} = \frac{T_{affected}}{improvement factor} + T_{unaffected}$$

- Example: multiply accounts for 80s/100s
 - How much improvement in multiply performance to get 5× overall?

$$20 = \frac{80}{n} + 20$$
 Can't be done!

Corollary: make the common case fast

Summary Remarks

- Cost/performance is improving
 - Due to underlying technology development
- Hierarchical layers of abstraction
 - In both hardware and software
- CPU execution time: the best performance measure
- Power is a limiting factor
 - Use parallelism to improve performance
- Instruction set architecture (ISA)
 - The hardware/software interface
